Abstract: In this study, the novel hybrids sulfonamide carbamates were synthesized by treatment of N-substituted 4-isothiocyanatophenyl sulfonamides with ethyl carbamate in dry 1,4-dioxane at reflux temperature in the presence of triethylamine. Also, treatment of Phenylacetethylisothiocyanate with sulfanilamide in refluxing acetonitrile afforded the corresponding hybrid sulfonamide acylthiourea derivatives. The anti-microbial activities of the synthesized compounds were evaluated. Ethyl (4-[(5-methyl-1,2-oxazol-3-yl)sulfamoyl]-phenyl[carbamothioyl]-carbamate and 2-Phenyl-N-((4-(N-thiazol-2-yl)sulfamoyl)-phenyl}[carbamothioyl]-acetamide exhibited the best activity against tested bacteria. Molecular docking studies for the final compounds were performed using the Open Eye docking suite. Moreover, Ligand efficiency (LE) and lipophilic ligand efficiency (LLE) parameters for Ethyl (4-[(5-methyl-1,2-oxazol-3-yl)sulfamoyl]phenyl[carbamothioyl]-carbamate and 2-Phenyl-N-((4-(N-thiazol-2-yl)sulfamoyl)phenyl]carbamothioyl)acetamide were evaluated. Quantum chemical calculations based on density functional theory (DFT) have been performed.

Keywords: Thiourea; carbamate; isothiocyanate; sulfonamide and Molecular docking.

Introduction

The synthesis of hybrid molecules and their evaluation as diverse range of pharmacological agents and as potent drugs has been under constant escalation for the last two decades. The hybrid molecules, obtained by the combination of structural features of two differently active fragments, are the most popular chemical entities to work upon for developing modified scaffolds with many improved and amazing properties in the area of biology as well as medicinal science. Sulfonamides drugs are very common compounds present in literature with massive activities. Some important sulfonamide derivatives are used as carbonic anhydrase inhibitors of commercial importance. Over 30 drugs containing this functionality are in clinical use, including anti-hypertensive agent bosentan, anti-bacterial, anti-protozoal, anti-fungal, anti-inflammatory, non-peptide vasopressin receptor antagonists and translation initiation inhibitors. They are also effective for the treatment of urinary, intestine, and ophthalmic infections, scalds, ulcerative colitis, rheumatoid arthritis, male erectile dysfunction as the phosphodiesterase-5 inhibitor sildenafil, obesity, and more recently as anticancer agents.

Prodrug sulfonamides are very important in the current medicinal protocol for sulfonamide therapy. For example, sulfonyl succinyl acts as a prodrug of sulfathiazole. It used in gut infections as it ionized in the alkaline conditions of the intestine and slowly hydrolysed by enzymes in the gut. Amid group lowers the polarity of the sulfonamide and increases the hydrophobic character. It allows the drug to cross the gut wall more easily and metabolised by enzymes (e.g. peptidases) in vivo to generate the primary amine. Primary amine ionizes and can form ionic interactions ionized primary amine also acts as a strong hydrogen bond (HB).

The carbamate group is a key structural motif in many approved drugs and prodrugs. There is increasing use of carbamates in medicinal chemistry, and many derivatives are specifically designed to make drug target interactions through their carbamate moiety. The carbamates emerging role in medicinal chemistry is also due to its chemical stability and its capability to increase permeability across cellular membranes. These attributes of organic carbamates have been exploited in drug design.

In recent years, several reports have indicated that carbamate linkage present in between the active pharmacophores of various structurally diverse molecules increases manifold biological activities of semi-synthetic/synthetic, natural/synthetic molecules. Furthermore, the role of carbamate linkage have been extensively studied in structurally diverse natural/semi-synthetic molecules against various disease such as anti-cancer, antibacterial, anti-fungal, anti-malarial, anti-viral, anti-HIV, anti-estrogenic, anti-progestational, anti-osteoporosis, anti-inflammatory, anti-filarial, anti-tubercular, ant-diabetic, anti-obesity, anti-convulsant, antihelminths and Alzheimer disease.

Other uses of carbamates are well known. Particularly, the employment of carbamates in various industries as agrochemicals, in the polymer industry, and also in peptide synthesis. Also, among the various amine protecting groups, carbamates are commonly used to enhance their chemical stability toward acids, bases, and hydrogenation.

Thiourea derivatives and thiourea hybrid with other functionality are useful compounds as precursors for the synthesis of different classes of acyclic and heterocyclic compounds. They have been employed as an anti-inflammatory, antimicrobial, antimalarial, pesticidal, and anticancer agents. The derivatives of thiourea represent one of the most promising classes of anticancer agents with a wide range of activities against various leukaemia and solid tumors.

Thiocarlide is a pharmacologically important thiourea drug that is used as a therapeutic agent in the treatment of tuberculosis and Phenethylthiazoylthiourea (PETT) derivatives (LY73497 and trovirdine HCl) have been discovered as potent inhibitors of HIV type 1. The development of microbial resistance to presently available antibiotics led the search for new antimicrobial agents. Due to the problem of microbial resistance to antibiotics, attention is given toward biologically active components isolated from natural products, as they may offer a new source of antimicrobial activities. In this interesting result, small molecules should contain some requirements as an amine group, be an amphiphilic and rigid, and have low globularity. Such information will assist us to design our compounds. It is important to examine the something that correlates between the activity of the compounds and their structures it is the quantum chemical calculation.

Figure 1: a) reported drugs contain sulfonamide prodrug as antimicrobial; b) general formula of our designed compounds.
In general, the HOMO possesses an antibonding character between the consecutive subunits, whereas the LUMO generally shows a bonding character between the subunits. No direct correlation between HOMO or LUMO energies and antibacterial activities is highlighted. The gap in energy between the HOMO and LUMO is an important stability index. Generally, the high stability indicates low chemical reactivity and small gap indicates high chemical reactivity. Softness (S) may be a property of a molecule that measures the extent of chemical reactivity. The chemical hardness (η) was related with the resistance towards the deformation of deformation cloud of chemical systems below little perturbation occurred. A small hardness means the compound features high polarizability. Polarizability (α) measures the pliability of electrons in an exceedingly very molecule to maneuver merely as a result of data. The softer a molecule is, the upper is its average polarizability.

In the frame of previous data, we thought to design new derivatives of prodrug sulfonamides. Our strategy was designed base on linking the amino group with more labile pharmacophore than reported amide, (Figure 1).

We finally decided to install the interesting hybrid functionality from thiourea and carbamate. The thiourea was tethered with ethyl carbamate or acyl benzyl to examine the effect of the aliphatic or aromatic side chain. On the other side at sulfonamide head, we studied varieties of heterocyclic rings. Herein is verified a direct correlation between compound structures and their biological activities based on different parameters.

Experimental

Materials and methods

All analyses were done at the Microanalytical Center, Cairo University, Cairo (Egypt). Melting points (uncorrected) were determined in open capillaries on a Gallenkamp melting point apparatus (Sanyo Gallenkamp, Southbrough, UK). IR spectra (KBr discs) were recorded using Schimadzu FT-IR 8400S spectrophotometer (Shimadzu, Kyoto, Japan). NMR Spectra were recorded on a Bruker spectrophotometer (Bruker, Karlsruhe, Germany). 1H spectrum was run at 300 MHz, and the 13C spectrum was run at 100 MHz in deuterated dimethylsulfoxide (DMSO-d6). Chemical shifts (δ) are reported relative to MS as an internal standard. Mass spectral data were given by a GCMS-QP1000 EX-spectrometer (Shimadzu, Kyoto, Japan) at 70 eV. Elemental analyses were done on a model 2400 CHNSO instrument (Perkin Elmer, Waltham, MA, USA). All reagents used were of the Analytical grade.

General Procedure for Synthesis of carbamates 3a-e

Method A: A mixture of ethyl carbamate (0.01 mol) and isothiocyanate2 (0.01 mol) and triethyl amine (0.01 mol) in 1,4-dioxane (10 mL) was refluxed for 3 h. The reaction mixture was left to cool at room temperature. The solid product, so formed, was collected by filtration and recrystallized from an appropriate solvent.

Method B: A mixture of 1 (0.01 mol), ethoxycarbonyl isothiocyanate (0.01 mol) prepared by adding ammonium thiocyanate (0.01 mol) to a solution of ethyl chloroformate (0.01 mol) in 1,4-dioxane (10 mL) and heat for 1/2 h followed by isolation of the byproduct, ammonium chloride] and triethylamine (0.01 mol) was refluxed for 1 h. The resulting solid product was collected by filtration and recrystallized to give 3.

Ethyl[(4-sulfamoylphenyl)carbamothioyl]-carbamate 3a.

White crystals (ethanol), Yield: (meth. A = 82 %, meth. B = 78 %), m.p. 203-204°C; IR (KBr, cm−1): 2959 (CH-aliph), 1711 (C=O), 1537 (C=S), 1371, 1162 (SO2); 1HNMR (DMSO-d6): 1.27 (t, 3H, CH3), 4.17 (q, 2H, CH2), 7.17 (s, 2H, SO2NH2 exchangeable with D2O), 7.42–7.83 (2d, 4H, Ar-H), 11.32, 11.68 (2s, 2H, 2NH, exchangeable with D2O); 13CNMR (DMSO-d6): 14.56 (CH3), 60.9 (CH2), 118.11, 124.74, 127.18, 131.39 (aromatic C), 153.9 (C=O) and 179.38 (C=S); Anal. **General procedure for the synthesis of acylthioureas 7a-e**

A solution of phenylacetyl chloride 5 (0.01 mol) and ammonium thiocyanate (0.01 mol) in acetonitrile (10 mL) was heated under reflux for 10-20 min. After the reaction mixture was cooled to room temperature and the formed precipitate (NH4Cl) was filtered off. To the freshly prepared solution of Phenylacetylthiocyanate 6, sulfanilamide 1 (0.01 mol) was added, and the mixture was refluxed for 2 h. Upon completion of reaction (checked by TLC), the resulting precipitate was collected by filtration and recrystallized to give the product 7.

**Results and discussion**

**Chemistry**

Isothiocyanates are useful and widely used building blocks in the synthesis of nitrogen, sulfur and oxygen heterocyclic and organometallic compounds of academic, pharmaceutical and industrial interest 50. The high electrophilicity and nucleophilicity related to the carbon and sulfur atoms, severely, of the isothiocyanates and their extended π electron system, create them distinctive precursors of an outsized type of target molecules. Consequently, many classes of five and six-membered nitrogen and sulfur heterocyclic, either carrying various substituents or fused with benzo or non-benzo nuclei to interesting poly heterocyclic, have been synthesized from isothiocyanates which are undoubtedly a landmark in organ sulfur chemistry 51. The intermediate, N-substituted 4-isothiocyanatophenyl sulfonamides 2 used for the preparation of target compounds have been synthesized in high yield via thiosphogenation of sulfonamides 1 at room temperature in the presence of dilute hydrochloric acid, according to literature procedure 52 (Scheme 1). The synthetic route designed for the carbamates 3a-e containing sulfonamide moiety is outlined in (Scheme 2).

The treatment of N-substituted 4-isothiocyanatophenyl sulfonamides 2a-e with ethyl carbamate in dry 1,4-dioxane at reflux temperature in the presence of triethylamine afforded the novel hybrid carbamates 3a-e.

The structure of all newly synthesized carbamate derivatives 3a-e was determined by analytical and spectroscopic analysis, which were consistent with the proposed structure. Carbamates 3a-e were confirmed by the absence of characteristic infrared absorption peak at 2000~2200 cm⁻¹ (N=C=S group). Also, the infrared spectra of the isolated compounds 3a-e contained absorption bands 3349~3150 cm⁻¹ due to stretching vibrations of the NH group and at 1736~1711 cm⁻¹ for the carbonyl group in addition to the presence of sulfamoyl and thiocarbonyl groups. For example, the ¹H NMR spectrum of compound 3a (DMSO-d₆) revealed a triplet signal at δH 1.27 ppm and a quartet at δH 4.17 ppm assigned to the ethyl group and a broad singlet at δH 7.41 ppm assigned for the NH₂ and two doublet signals at δH 7.42~7.83 ppm assigned to the aromatic protons. Also, in the ¹H NMR spectrums; two N−H protons at δH 11.32 and 11.68 ppm appeared as singlet signals. These are the most deshielded signals because of intramolecular hydrogen bonding that results in shifting the signals functional of Lee, Yang and Parr (LYP). It has fewer convergence problems than those found in the pure DFT methods. Thus, B3LYP has been used in this paper to carry out quantum calculations. Full geometry optimizations of all additivities were carried out with the standard B3LYP/6-311G++ (d, p) basis set using Gaussian 09.

**Docking studies**

Crystallographic structure for dihydropteroate synthase (DHPH) (ID: 3TZF) 57 contains the standard sulfamethoxazole co-crystalized inside the receptor was chosen for docking. A library of our designed sulfonamides linked thiourea-carbamate including standard drugs was designed, and energy minimized using MMFF94 force field calculations the catalytic domain of DHPS which was obtained from protein data bank (PDB code 3TZF) and was prepared for docking using Open Eye 58-60 software. Omega application was used to prepare conformers for docking, and FRED application was selected to generate a physical property (ΔG) reflecting the predicted energy profile of the ligand-receptor complex.
towards higher ppm value, thus justify the presence of thio core in thiourea. In the $^{13}$C-NMR spectral data of compounds 3a, c, e the thiocarbonyl group of thiourea moiety was also observed at around $\delta$C 169-170.38 ppm and carbonyl carbon appeared at around $\delta$C 153.4-153.9 ppm. Moreover, the mass spectral data of compounds 3b-d were fully consistent with the assigned structures. The molecular ion peaks of synthesized compounds 3b, 3c and 3d were observed at m/z 345(3.38%), 386(2.06%) and 384(46%) which compatible with its molecular weights, respectively. The molecular ion peak of compound 3c underwent fragmentation to produce a peak at m/z 297 (44%), corresponding to the molecular ion of N-(2-thiazolyl)-4-thiocyanato phenyl sulfonamides. It underwent further loss of SO$_2$, phenyl isothiocyanate and 2-thiazolyl sulfamoyl yielded peaks at m/z 233(58.45%),163(1.58%) and 134 (100%; base peak), respectively.

Scheme 1. synthesis of p-substituted sulfamoylphenylisothiocyanate 2a-e

Scheme 2. synthesis of carbamates 3a-e containing sulfonamide moiety

The formation of carbamate 3 can be explained by the reaction pathway depicted in (Scheme 3). The formation of 3 is assumed to proceed via the nucleophilic attack of the amino group of the ethyl carbamate on thiocarbonyl group of isothiocyanate to form the intermediate (A), followed by deprotonation and protonation to yield the carbamate skeleton. A further evidence for the formation of carbamate 3 was obtained by an independent synthesis of compound 3a via treatment of sulfanilamide 1 with ethoxycarbonylisothiocyanate 4 in 1,4-dioxane in the presence of a catalytic amount of triethylamine to yield a product identical in all respect (mp. TLC and spectra) with that obtained previously from reaction of 2a with ethyl carbamate (Scheme 2). The physical properties, spectral information, and mass analysis of all the synthesized compounds 3a-e are illustrated in the experimental section.
The chemistry of acyl isothiocyanates is very rich and diverse and has been employed in the synthesis of some biologically important organic compounds. In recent years, 1-(acyl/aroyl)-3-(substituted)thioureas have been seen increasing importance in organic chemistry with privileged structures. They have been the subject of extensive study in coordination chemistry, and are also known to play a promising role in the fields of material sciences, molecular electronics, molecular recognition, agriculture, biological activities and pharmaceuticals.

Phenylacetylisothiocyanate was prepared in situ by reaction of Phenylacetyl chloride with an equimolar quantity of ammonium thiocyanate in dry acetonitrile. Treatment of Phenylacetylisothiocyanate with sulfanilamide in refluxing acetonitrile afforded the corresponding acylthiourea derivatives.

Scheme 3. The proposed mechanism for the formation of carbamates 3a-e

Scheme 4. Synthesis of acetamides containing sulfonamide moiety

The structures of acylthiourea derivatives were established by their elemental analysis and spectral data. The infrared spectra of compounds 7...
indicated the characteristic absorption bands at 1690-1713 cm$^{-1}$ for the C=O group in addition to the presence of NH, C=S and SO$_2$ groups. The $^1$HNMR spectral data were also consistent with the assigned structures. For example, the $^1$H NMR spectrum of compound 7c (DMSO-$d_6$) showed a singlet signal at $\delta_H$ 2.28 ppm assigned to the methyl protons, a singlet signal at $\delta_H$ = 3.81 ppm assigned to the methylene protons, a singlet signal at $\delta_H$ 6.14 ppm due to proton of isoxazole ring in addition to the presence of aromatic protons. Also, in $^1$H NMR the characteristic broad signals at $\delta_H$ 11.43 and 12.57 ppm for protons of $N_1$ and $N_3$, respectively. In the mass spectrum of compound 7a, 7c and 7d molecular ion peaks were observed at m/z 349 (38.68%), m/z 430 (0.5%) and m/z 444 (1%) which compatible with its molecular weights.

A plausible mechanism for the synthesis of acyl thioureas 7a-e is depicted in (Scheme 5).

Scheme 5. The proposed mechanism for the synthesis of acyl thioureas 7a-e

Figure 2. The minimum inhibitory concentration of 7b and 3d on Bacillus subtilis

Antimicrobial activity
The in vitro antimicrobial activities of the synthesized compounds were evaluated for four Gram-positive bacteria viz. Staphylococcus aureus, Methicillin-Resistant Staphylococcus aureus (MRSA), Bacillus subtilis, Streptococcus pyogenes, and three Gram-negative organisms viz. Escherichia coli, Proteus vulgaris, Erwiniacarotovora, as well as one fungi viz. Candida Albicans by agar well diffusion method. Ampicillin and penicillin were used as standards. The antibacterial and antifungal data were depicted in Table 1. Compounds 7b and 3d exhibited
appreciable broad spectrum (87.5%) against both Gram-positive bacteria and Gram-negative bacteria (Figure 3), followed by 2e (37.5%, each) then 7a, 7c, and 3e (25%). The pathogen S. aureus was the most sensitive bacteria in case of 7a (1.4 mm diameter of inhibition zone), whereas, Proteus vulgaris was the most sensitive in case of 3d (1.3 mm diameter). Compounds 7b and 3d were selected for determination of MIC as the highest for inhibition the growth of Bacillus subtilis. The minimum inhibitory concentration of 7b and 3d on Bacillus subtilis were 70 and 80 μ/ml, respectively, (Figure 2).

Docking Study
Sulfonamides drugs are reported to inhibit bacterial dihydropteroate synthase (DHPS) which has an important role in the biosynthesis of the tetrahydrofolate cofactor which is crucial to pyrimidine and DNA biosynthesis.

Crystallographic structure for dihydropteroate synthase (DHPS) (ID: 3TZF) 57 illustrated that the active site region contains the standard sulfamethoxazole co-crystallized inside the receptor with the formation of hydrogen bonding (HB) with amino acids Lys 221 AA, Ser 222 AA, and Ther 62 AA through its sulfonamide and para-amino group. Also, benzene ring form π-π bonding interactions with amino acids Arg 63, Pro 64 57. The docking of our target compounds with (DHPS) represents consensuses scores and binding modes correlated with their biological activity as antimicrobial. A library of our designed sulfonamides linked thiourea-carbamate including standard drugs was designed. The catalytic domain of DHPS which was obtained from protein data bank (PDB code 3TZF) was prepared for docking using Open Eye 58-60 software. To validate our docking, the study commenced with docking with standard sulfamethoxazole and another standard which showed docking pose and a mode similar to co-crystalized pose 57. The active compound 3d (sulfamethoxazole linked thiourea-ethyl carbamate) lays in the active sit with the formation of four HBs; two HBs with Ser 222 AA through both sulfonamide and nitrogen of isoxazole ring (acceptor). Also forms HB with Arg 225 AA through the thiourea part (acceptor). The carbonyl of ethyl carbamate group interacts with Thr 62 though the formation of HB (acceptor), (Figure 3).

Figure 3. A visual representation for 3d docked with PDB: 3TZF showing three HBs interaction towards the binding site.
Compound 7c (sulfamethoxazole linked thiourea-benzyl carbamate) forms one HB (in comparison 3d) with Ser 222 AA through the sulfur of thiourea. Sulfonamide and oxygen of isoxazole form HB with Arg 255 AA. The nitrogen of isoxazole forms HB with Lys 221 AA, (Figure 4).

![Figure 4](image1.png)

**Figure 4.** A visual representation for 7c docked with PDB: 3TZF showing Two HBs interaction towards the binding site.

Judging from the docking study, both analogues 3d and 7c have different docking mode and pose. The R (ethyl or benzyl) group from carbamate part has a great effect, and this explains the difference in activity. Compound 7b docked with the receptor with formations of different hydrogen bonding; with Ser 222 AA through it Sulfur and NH of thiourea as acceptor and donor, respectively. The sulfonamide forms HB with Arg 255 AA. The thiazole ring forms HB through its nitrogen atom with Lys 221 AA, (Figure 5).

![Figure 5](image2.png)

**Figure 5.** A visual representation for 7b docked with PDB: 3TZF showing HB interaction towards the binding site.

Among the synthesized compounds, the benzyl group forms hydrophobic-hydrophobic interaction while the ethyl group in ethyl carbamate facilitate the formation of HB interactions. In order to understand the effect of a heterocyclic ring, compounds 7d and 7c were examined. Unfortunately, both compounds differ in the docking pose and mode. Compound 7d forms hydrophobic-hydrophobic interaction without formation of HB. Although both compounds 3d and 3c form HB with an essential amino acid for binding, both have different poses.

**Calculation of Ligand efficiency (LE) and Ligand lipophilic efficiency (LLE)** [61]

**Ligand efficiency (LE) scores:**

ADMET (Absorption, Distribution, Metabolism, Excretion and Toxicity) properties are important in drug discovery and were calculated, with special...
emphasis on the lipophilicity requirements. LE is used in fragment-based drug discovery to lead compounds with optimal combinations of physicochemical properties and pharmacological properties. LE is used to estimate the efficiency of compounds and determine binding affinity about the number of heavy atoms in a molecule. This provides a way to compare the affinity of molecules corrected for their size.

**Ligand-lipophilicity efficiency (LLE)**

LLE describes how efficient a ligand exploits its lipophilicity. If lipophilicity is too high, the likelihood of a compound to bind to multiple targets increases. Moreover, affinity is often optimized through the introduction of lipophilic groups, as these contribute favorably to the hydrophobic effect without the need for specific interactions with the target. These contrast with polar groups, which need to establish very good interactions with the target to compensate for the desolvation penalty. For this reason, polar groups are often used to improve solubility rather than affinity.

The quantum chemical calculation of the prepared compound (3b, d, e and 7a-e) was tabulated in Table 3. These data proved the AHE is less value in compound 3d and 7b that indicate that the two compounds are more active than another compounds. As soon as the softness value showed the high value in the same compound 3d and 7b that indicate that the two compounds highly active. From the foregoing, we find that quantum calculated data is fully compatible with biological activities. The theoretical study implies that gap, softness and hardness tend to be the best chemical descriptors to identify compounds presenting an interesting antibacterial activity. The reaction of inhibition in question seems to be mainly directed by hard-hard interactions, for example, the transfer of a proton to a hard base. In that case, the reactions are mainly controlled by electrostatic relationships as modelled by Mulliken charges that can be also considered as important descriptors.

**Quantum chemical calculations**

The ultimate goal of the structure-activity relationship (SAR) studies is to correlate the biological activity of a series of compounds with their structures. Unconstrained geometry optimizations of prepared compounds (3b, d, e and 7a-e) were carried out at gradient corrected DFT using Becke’s three parameters hybrid method and the Lee-Yang - Parr correlation functional (B3LYP) combined with 6-31G(d) basis set using Gaussian 09 in both gas and solvent (DMSO) media. Figure 6 shows HOMO and LUMO frontier orbital's obtained for the studied compounds. It is important to examine the HOMO and LUMO for these compounds because the relative ordering of occupied and virtual orbital provides a reasonable qualitative indication of electronic properties. Molecular electrostatic potential mapping is very useful in the investigation of the physicochemical properties of the studied compounds. Different values of the electrostatic potential at the surface are represented by different colors: red represents regions of most electro negative potential, blue represents regions of most positive electrostatic potential and green represents regions of zero potential. Herein, the three MESPs are very similar and revealed that the high electronic density suitable for the electrophilic attack is located on sulfonyl oxygen atoms in the red region.

Conclusion

The present study describes the synthesis, structure elucidations, in-vitro anti-microbial activity assay and molecular docking of new sulfonamide hybrids. A series of new sulfonamide carbamates hybrids were synthesized by treatment of N-substituted 4-isothiocyanatophenyl sulfonamides with ethyl carbamate. Also, the novel hybrids sulfonamide–acylthiourea derivatives were obtained by treatment of Phenylacetylisothiocyanate with sulfanilamide. The structures of all the title products were elucidated by spectroscopic data, IR, NMR (1H and 13C NMR) and mass and elemental analyses. The in vitro anti-microbial potential of all the synthesized compounds were investigated. It is evident that synthesized compounds Ethyl[(4-{(5-methyl-1,2-oxazol-3-yl)sulfamoyl}-phenyl)carbamothioyl] carbamate and 2-Phenyl-N-{(4-(N-thiazol-2-yl)sulfamoyl)-phenyl)carbamothioyl)-acetamide have good antimicrobial activity. Molecular docking studies for the final compounds were performed using the Open Eye docking suite. Moreover, Ligand efficiency (LE) and lipophilic ligand efficiency (LLE) parameters for Ethyl[(4-{(5-methyl-1,2-oxazol-3-yl)sulfamoyl}-phenyl)carbamothioyl]-carbamate and 2-Phenyl-N-[(4-(N-thiazol-2-yl)sulfamoyl)phenyl)carbamothioyl]acetamide were evaluated. Quantum chemical calculations based on density functional theory (DFT) have been explored.

Conflict of interest

The authors declare that they have no conflict of interest.
